We introduce a *future orientation index* to quantify the degree to which Internet users worldwide seek more information about years in the future than years in the past. We analyse *Google* logs and find a striking correlation between the country's GDP and the predisposition of its inhabitants to look forward.

Recent years have witnessed a revolution in the social sciences. Mammoth amounts of data are now being generated through society's extensive interactions with technological systems, automatically documenting collective human behaviour in a previously unimaginable fashion¹⁻³. Analysis of such "big data" opens up new opportunities for a more precise and extensive quantification of real world social phenomena that was difficult to attain using complicated and expensive surveys and laboratory experiments alone.

A particularly fruitful area of research has focused on the analysis of Internet user search queries, as logged by search engines such as *Google*. Strong links have been found between changes in the information users are seeking online and events in the real world, ranging from reports of flu infections across the USA⁴ to the trading volume in the US stock markets⁵.

Interdependencies among social entities distributed worldwide are growing, a development with repercussions for the way our world works⁶. However, research based on search engine queries has to date offered insight into behaviour only within distinct linguistic silos, due to its reliance on keyword analysis, and the thousands of different languages spoken in our linguistically varied world.

Results

In this study, we present a cross-country analysis of search engine queries, and demonstrate a strong link between behaviour online and real world economic indicators. By considering searches for years represented in Arabic numerals, an almost ubiquitous written representation, we can evaluate worldwide interest in years in the future (such as "2013") and years in the past (such as "2011"). These representations have previously been considered in an investigation of a large corpus of text from books, where analysis suggested that authors' interest in the past has decreased over time⁷. Here, we compare the predisposition of Internet users in different countries to look more to the future, or more to the past. We find that the online "*future orientation*" of a country is strongly correlated with the country's per capita gross domestic product (GDP).

For these reasons, we calculate the ratio of the volume of searches made for the coming year (represented in Arabic numerals) to the volume of searches for the previous year and call this value the *future orientation index* (Fig. 1a). We compute the *future orientation index* for each of 45 countries with data from the search engine *Google* for users located in the country in question from the year 2010, using the search terms "2009" and "2011". The *Google Trends* service from which these data are taken does not report absolute search volumes, but scales these volumes according to the average search volume for the first term in each data request. For each country, we therefore request the search volumes for all terms simultaneously, to ensure that these volumes are comparable. We compare the *future orientation index* to the country's per capita GDP, calculated on a purchasing power parity basis, which we retrieve from the *CIA World Factbook* which provides figures as of 1 July 2010. Our analysis considers countries for which both *Google Trends* and the *CIA World Factbook* provide data, and to reduce noise excludes countries with fewer than five million Internet users, for which few search data are available. We uncover a strong tendency for countries in which *Google* users enquire more about the future to exhibit a larger per capita GDP (Fig. 1b; Pearson correlation coefficient $r = 0.78$, $df = 43$, $p < 0.001$). We investigate the robustness of the *future orientation index* by considering search data from earlier years. The ratio calculation that this index is based

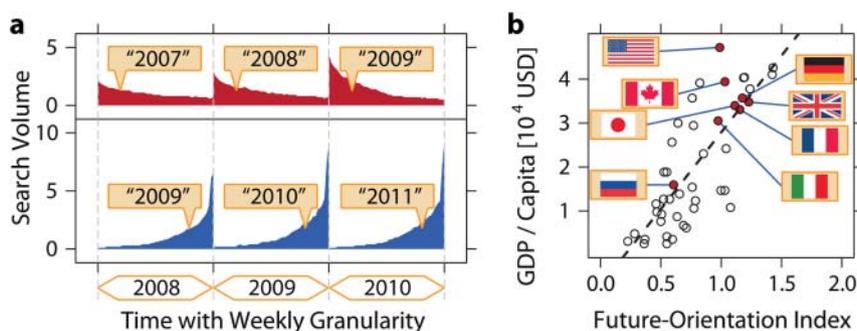

Figure 1 | The *future orientation index*, and its correlation with per capita GDP. (a) The frequency with which *Google* users worldwide search for information about the previous year (in red) and the following year (in blue). Data are plotted for each of 52 weeks per year. The *future orientation index* for a given year (e.g., 2010) is calculated as the ratio of the total number of searches for the following year (“2011”) to the total number of searches for the previous year (“2009”). (b) The *future orientation index* for 45 countries based on searches in 2010, compared with per capita GDP. We demonstrate a strong tendency for countries in which *Google* users enquire more about the future to possess a larger per capita GDP (Pearson correlation coefficient $r = 0.78$, $df = 43$, $p < 0.001$).

on allows it to absorb any overall increase or decrease in the volume of searches from year to year. We find similar relationships between the *future orientation index* and per capita GDP in 2010 for calculations of the index with search data from 2009, using the search terms “2008” and “2010” ($r = 0.64$, $df = 43$, $p < 0.001$), and for calculations of the index with search data from 2008, using the search terms “2007” and “2009” ($r = 0.53$, $df = 43$, $p < 0.001$).

Discussion

In this study, we have introduced the *future orientation index*, which quantifies to what extent Internet users worldwide are seeking information about the future rather than the past. The analysis described here shows that the value of this index for 45 countries in 2010 is correlated with a key economic indicator, per capita GDP. Our results are consistent with the intriguing possibility that there is a relationship between the economic success of a country and the information seeking behaviour of its citizens online. We highlight two potential explanations for such a relationship. Firstly, these findings may reflect international differences in attention to the future and the past, where a focus on the future supports economic success. Secondly, these findings may reflect international differences in the type of information sought online, perhaps due to economic influences on available Internet infrastructure. We suggest that the *future orientation index* may be productively applied to further spatial and temporal divisions, and compared with further social and economic indicators, to help develop an Internet data driven image of worldwide society today.
